Custom Controls & Custom Validation

Angular 2 – Types of Forms

Template Driven Forms

Model Driven (Reactive Forms)

Angular 2 – Types of Forms

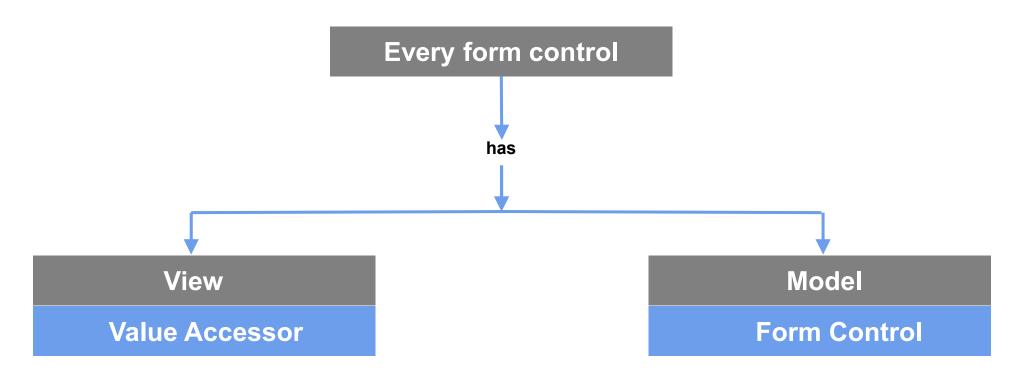

Template Driven Forms

- Source of truth is the Template
- Define templates. Angular generates form model o/t fly
- Less descriptive
- Quickly Build simple forms –
 Less control
- Less testable

Model Driven (Reactive Forms)

- Source of truth is the component class / directive
- Instantiate Form model and Control model yourself
- More Descriptive
- Code all the details. Takes more time, gives more control
- Very good testable

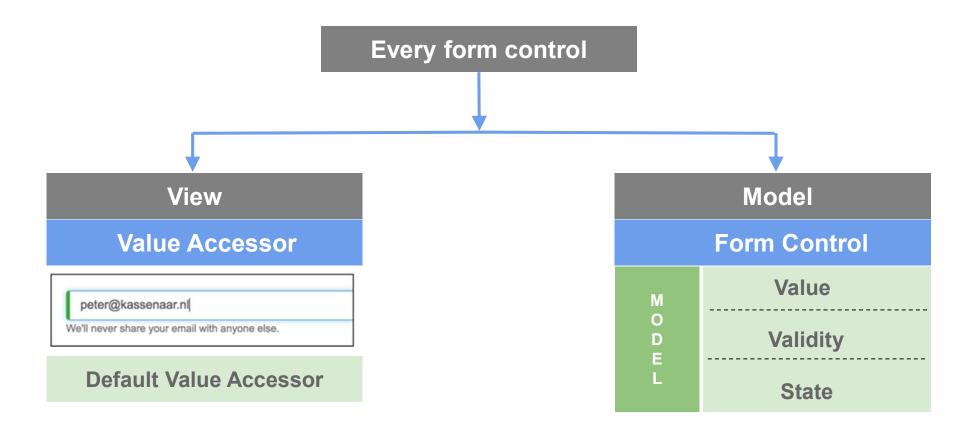

Angular 2 Forms - Fundamentals

Retrieves value from HTML controls

Maintains model in component

In more detail

Angular 2 Forms - Base class

```
export abstract class AbstractControl {
        value: any;
     private status: string;
     private errors: {[key: string]: any};
     private pristine: boolean = true;
     private touched: boolean = false;
     get value(): any { return this. value; }
     get valid(): boolean { return this. status === VALID; }
     abstract setValue(value: any, options?: Object): void;
```

Summary – what have we learned so far

1 2

Template Driven Forms

Less to code

Model Driven Forms

More to code

3

Model

Value/Validity/State

Angular 2 – Types of Forms

Template Driven Forms

Model Driven (Reactive Forms)

Let's build a template driven form!

• Step 1 - Add (or check) FormsModule in app/main.ts

```
import {platformBrowserDynamic} from '@angular/platform-browser-dynamic';
import {FormsModule} from '@angular/forms';
import {AppModule} from './app.module';
```

Step 2 - Add FormsModule to app.module.ts

```
import {NgModule} from '@angular/core';
import {BrowserModule} from '@angular/platform-browser';
import {FormsModule} from '@angular/forms';
import {AppComponent} from './app.component';
@NgModule({
  imports : [BrowserModule, FormsModule],
  declarations: [AppComponent],
   bootstrap : [AppComponent]
})
export class AppModule {
```

Step 3 – write form in HTML

```
<form novalidate>
   <div class="form-group">
      <label for="inputEmail">Email address</label>
      <input type="email" class="form-control" id="inputEmail"</pre>
            placeholder="Enter email" name="email">
      <small class="form-text text-muted">
         We'll never share your email with anyone else.
      </small>
   </div>
   <div class="form-group">
      <label for="inputPassword">Password</label>
      <input type="password" class="form-control" id="inputPassword"</pre>
            placeholder="Password" name="password">
   </div>
   <button type="submit" class="btn btn-primary">Submit</button>
                          This is just plain HTML. No Angular stuff here...
</form>
```

Step 4. Defining a Template Driven Form

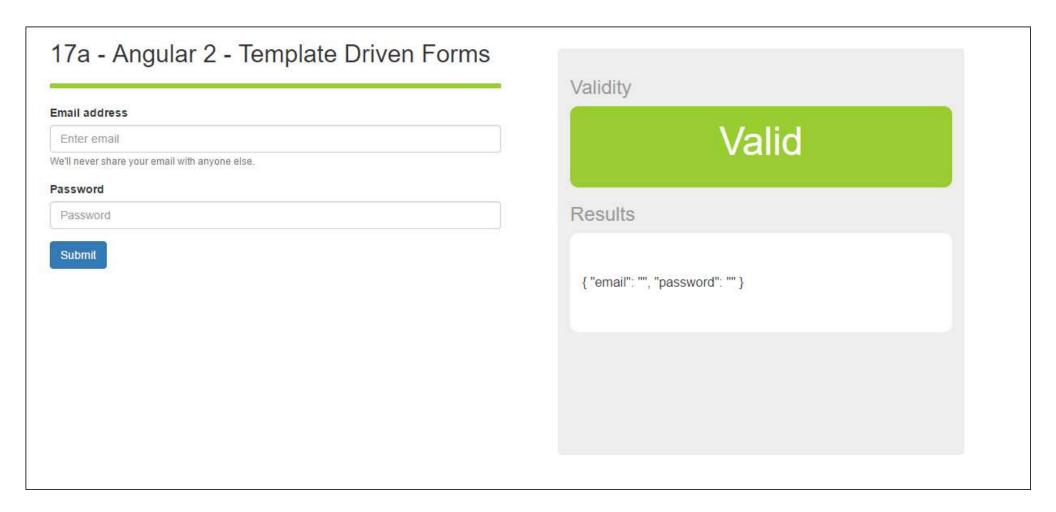

- Add #myForm="ngForm" to the <form> tag
 - This declares a local variable with the name #myForm to the <form> element. It is of type NgForm
- Add ngModel to each and every form field
 - No value necessary

Just checking - Sample results pane

Just to show runtime results of the Validity and Value of the form using

```
myForm.valid
myForm.value
```

Results so far

Checkpoint

- The #myForm exposes the value and the validity of the form as a whole.
- ngModel adds the individual controls to the #myForm.
- You can now check it's value and state in the results pane
- Try what happens if you remove one of the ngModel directives!

Check for yourself: the value of a form is a JSON-object.

Addressing individual controls

Retrieve values from individual controls

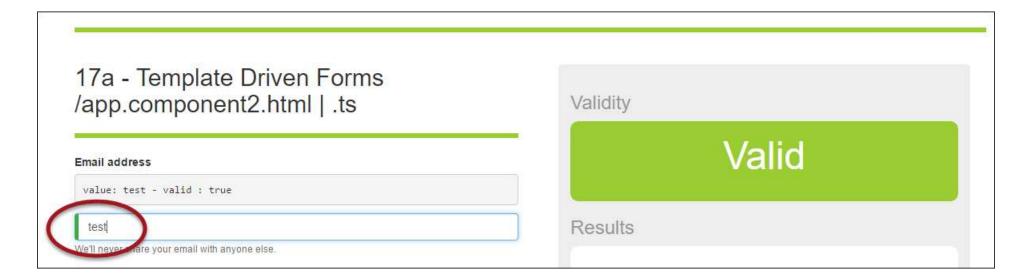

- Do the same as with the form
- Add for example #email="ngModel" to input field
- Now, the value, validity and state (i.e. its ValueAccessors!) are accessible through the local template variable

Required fields

- Add HTML5 attribute required to the input field.
- No checking on type yet!
 - It's just required.

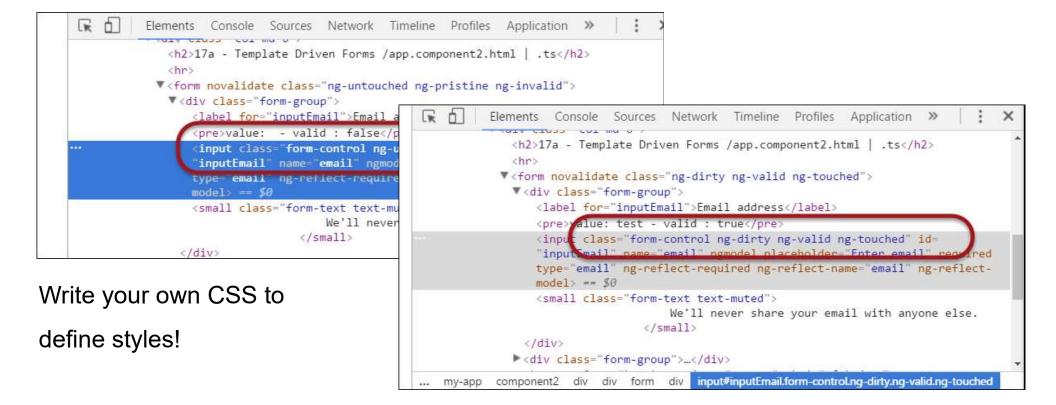

```
<input type="email" class="form-control" id="inputEmail"
    placeholder="Enter email" name="email" ngModel #email="ngModel" required>
```

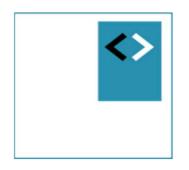

Angular classes and checks

- Angular adds classes to the rendered HTML to indicate state
 - ng-untouched / ng-touched,
 - ng-pristine / ng-dirty
 - ng-invalid / ng-valid

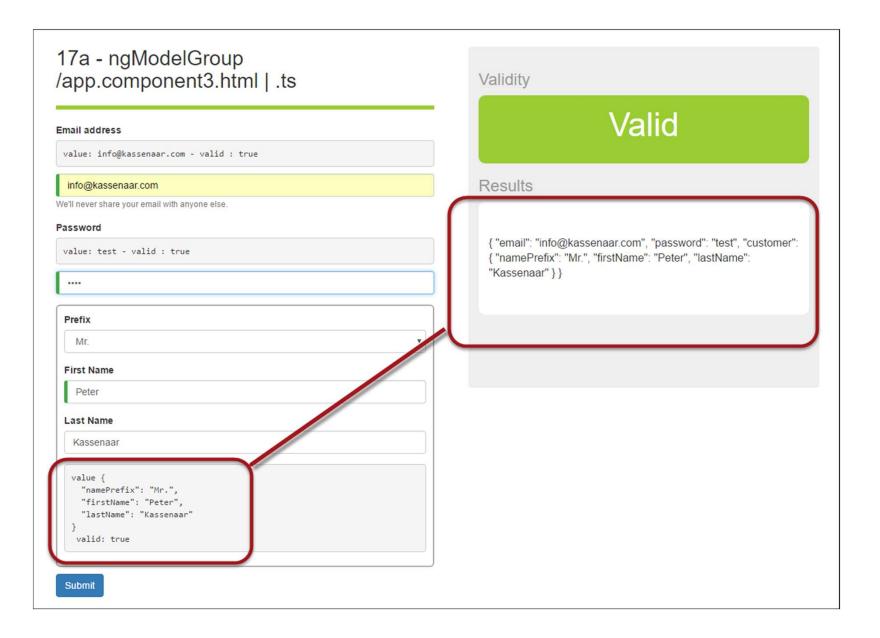

Using ngModelGroup

Adding ngModelGroup

Combining form fields into logical groups

Use a local template variable (i.e. #customer="ngModelGroup") only if you want to have access to the state and validity of the group as a wole.

ngModelGroup creates a nested object

Submitting forms

Define a (click) handler on the button

- Only activate the button if the form is valid
- Pass myForm as a parameter
- Note: no actual need for two-way databinding with [(ngModel)]

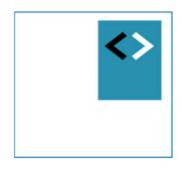

```
<button type="submit" class="btn btn-primary"
        (click)="onSubmit(myForm)"
        [disabled]="!myForm.valid">
        Submit
</button>
```

```
onSubmit(form){
   console.log('Form submitted: ', form.value);
   alert('Form submitted!' + JSON.stringify(form.value))
}
```

https://toddmotto.com/angular-2-forms-template-driven

Model Driven Forms

Or: Reactive Forms

Reactive Forms

- Based on reactive programming we already know
 - Events, Event Emitters
 - Observables
- Every form control is an observable!

```
export abstract class AbstractControl {
    ...
    private _valueChanges: EventEmitter<any>;
    ...
    get valueChanges(): Observable<any> {
        return this._valueChanges;
    }
    ...
}
```

Differences - key things to remember

- No more ngForm → use [formGroup]
- No more ngModel → use formControlName
- Import the ReactiveFormsModule
- Form state lives in the Component, not in the View
- Possible validations are in the Component, not in the View

- The view is not generated for you.
- You need to write the HTML yourself

Form Controls are observables

- Import & instantiate in the Component
- Build your model in constructor or ngOnInit.
- Listen to changes (.subscribe()) and act accordingly:

Subscribe to those observables

```
// 1. complete form
this.myReactiveForm.valueChanges.subscribe((value)=>{
   console.log(value);
});

// 2. watch just one control
this.myReactiveForm.get('email').valueChanges.subscribe((value)=>{
   console.log(value);
});
```

Building reactive forms

Step 1 – import ReactiveFormsModule

• app.module.ts

```
import {NgModule} from '@angular/core';
import {BrowserModule} from '@angular/platform-browser';
import {FormsModule, ReactiveFormsModule} from '@angular/forms';
import
@NgModule({
   imports : [
      BrowserModule,
      FormsModule,
      ReactiveFormsModule,
})
export class AppModule {
```

Step 2 - use [formGroup] and formControlName

Step 3 – Build your form in Component

```
export class AppComponent1 implements OnInit {
   myReactiveForm: FormGroup;
   constructor(private formBuilder: FormBuilder) {
   ngOnInit() {
      // 1. Define the model of Reactive Form.
      // Notice the nested formBuilder.group() for group Customer
      this.myReactiveForm = this.formBuilder.group({
         email
               : ``,
         password: ``,
         customer: this.formBuilder.group({
            prefix: ``,
            firstName: ``,
            lastName: ``
         })
      })
```

Subscribe to changes

```
ngOnInit() {
  // 2. Subscribe to changes at form level or...
   this.myReactiveForm.valueChanges.subscribe((value)=>{
      console.log('Changes at form level: ', value);
   });
  // 3. Subscribe to changes at control level.
   this.myReactiveForm.get('email').valueChanges.subscribe((value)=>{
      console.log('Changes at control level: ', value);
   });
```

Submitting a reactive form

- Can be based on .valueChanges() (though not very likely) for any given form control or complete form
- Use just .click() event handler for submit button

```
<button type="submit" class="btn btn-primary"
            (click)="onSubmit()"
            [disabled]="!myReactiveForm.valid">
            Submit
            </button>
```

```
onSubmit() {
   console.log('Form submitted: ', this.myReactiveForm.value);
   // TODO: do something useful with form
}
```

Form Validation

1. Validating Template driven forms

Use HTML5-attributes like required, pattern, minlength and so on.

Under the hood, these are actually Angular directives!

Angular adds/removes corresponding classes.

```
<input type="password" class="form-control" ngModel
    id="inputPassword" placeholder="Password" name="password"
#pw="ngModel" required minlength="6">
```

Validating reactive forms

No more declarative attributes required, minlength, maxlength and so on.

Add Validator on the component class instead.

Configure validator per your needs.

Angular 2 built-in validators

angular/modules/@angular/forms/src/validators.ts

```
export class Validators {
    static required(control: AbstractControl): {[key: string]: boolean} {
    static minLength(minLength: number): ValidatorFn {
    static maxLength(maxLength: number): ValidatorFn {
    static pattern(pattern: string): ValidatorFn {
    static nullValidator(c: AbstractControl): {
```

Adding default Validators

• Adding Validators to class definition

```
email : ['', Validators.required],
```

• Multiple validations? Add an array of Validators, using

```
Validators.compose()
```

```
this.myReactiveForm = this.formBuilder.group({
    email : ['', Validators.required],
    password: ['', Validators.compose([Validators.required, Validators.minLength(6)])],
    confirm: ['', Validators.compose([Validators.required, Validators.minLength(6)])],
    ...
});
```

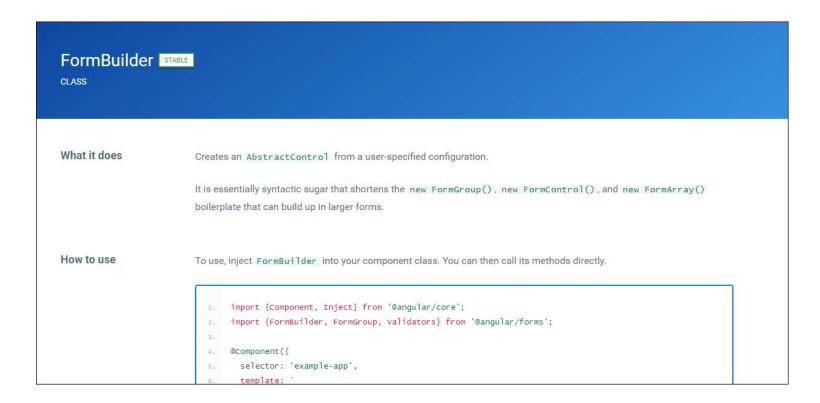

Adding Custom Validators

- Creating a Password-confirm validator
- Steps:
 - 1. Create a validation function, taking AbstractControl as a parameter
 - 2. Write your logic
 - 3. Don't forget: pass the function in as a configuration parameter for the group or form you are validating!

```
this.myReactiveForm = this.formBuilder.group({
   email : ['', Validators.required],
   password: ['', Validators.compose([Validators.required, Validators.minLength(6)])],
   confirm : ['', Validators.compose([Validators.required, Validators.minLength(6)])],
   },
   {validator: passwordMatcher} // pass in the validator function
);
```

More on FormBuilder class

- https://angular.io/docs/ts/latest/api/forms/index/FormBuilderclass.html
- Information on using and configuring FormBuilder

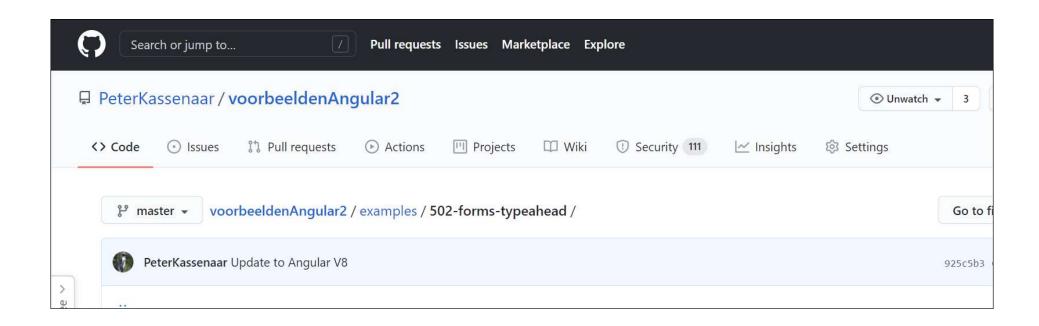

Subscribing to form events

Working with Observables (again). Typeahead demo

Example

• .../voorbeeldenAngular2/examples/502-forms-typeahead

Define a form

```
<form novalidate [formGroup]="searchForm">
   <div class="form-group">
      <label for="searchYouTube">Search YouTube</label>
      <input type="text" class="form-control" id="searchYouTube"</pre>
            formControlName="searchYouTube"
            placeholder="Search YouTube" name="search">
   </div>
</form>
```

Define component

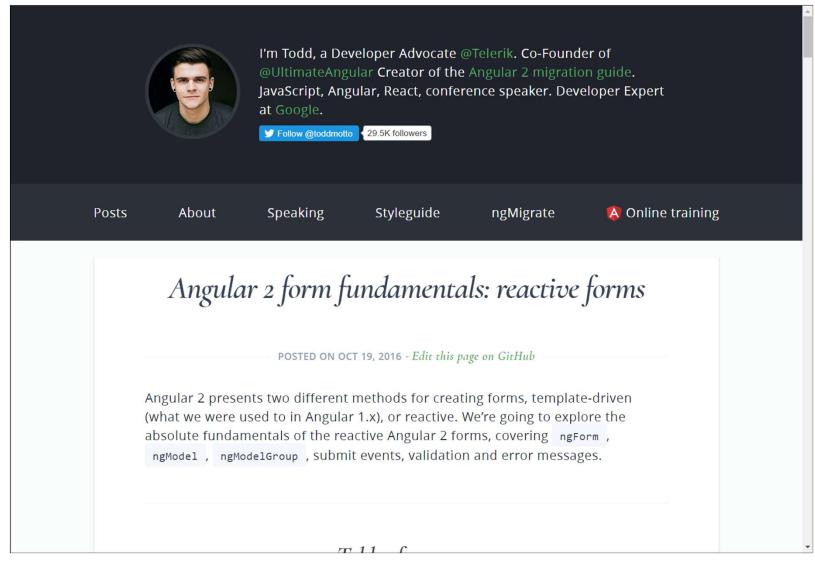

Compose a class, subscribe to .valueChanges() event

```
import {Http, Response} from '@angular/http';
import {Observable} from 'rxjs/Observable'
import {FormControl, FormGroup} from "@angular/forms";
// import just the operators we need, not import 'rxjs/Rx'
import 'rxjs/add/operator/map';
import 'rxjs/add/operator/switchMap';
import 'rxjs/add/operator/debounceTime';
// define some constants
const BASE URL = 'https://www.googleapis.com/youtube/v3/search';
const API KEY = 'AIzaSyBdi3LXzf1xWXOAVgAwNkGvjnM1TwSV4VU';
// compose a url to search for, based on a query/keyword
const makeURL = (query: string) => `${BASE_URL}?q=${query}&part=snippet&key=${API_KEY}`;
```

```
@Component({
   selector : 'component1',
  templateUrl: 'app/component1/app.component1.html'
})
export class AppComponent1 implements OnInit {
   videos: Observable<any[]>;
  // compose our form
   searchYouTube = new FormControl();
                = new FormGroup({
   searchForm
      searchYouTube: this.searchYouTube,
  });
   constructor(private http: Http) {
   ngOnInit() {
     // subscribe to Youtube input textbox and bind async (see html)
     this.videos = this.searchYouTube.valueChanges
         .debounceTime(600)
                                // wait for 600ms to hit the API
         .map(query => makeURL(query)) // turn keyword into a real youtube-URL
         .switchMap(url => this.http.get(url)) // wait for, and switch to the Observable that my http get call returns (mo
         .map((res: Response) => res.json()) // map its response to json
         .map(response => response.items); // unwrap the response and return only the items array
```

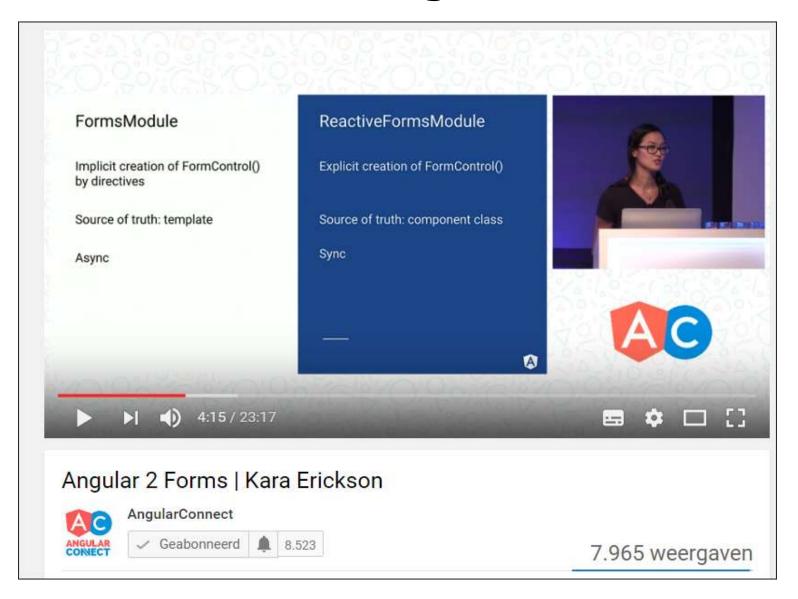

- See ../502-typeahead as an example
